1 Power law process (PLP)

1.1 PLP intensity function

Power law process (PLP): When the intensity function of a NHPP is:

$$\lambda(t) = \frac{\beta}{\theta} \bigg(\frac{t}{\theta}\bigg)^{\beta-1} = \beta \theta^{-\beta} t^{\beta},$$

where $\beta > 0$ and $\theta > 0$, the process is called the power law process (PLP). The mean function $\Lambda(t)$ is the integral of the intensity function:

$$\Lambda(t) = \int_0^t \lambda(t) dt = \int_0^t \frac{\beta}{\theta} \left(\frac{t}{\theta}\right)^{\beta - 1} = \left(\frac{t}{\theta}\right)^{\beta}$$

1.2 PLP simulation

```
t_new <- theta*s^(1/beta) # inverse of PLP intensity function
   t <- c(t, t_new)
  }
  t = t[c(-1, -length(t))]
  return(t)
# simulate multiple NHPPs - time truncated case
sim_mul_plp_tau = function(n_shift = 20,
                           shift_len_mean = 20, shift_len_sd = 5,
                           theta = 10, beta = 2, mean_n = 5){
  tau_vector = rnorm(n_shift, shift_len_mean, shift_len_sd)#difference1
  t_list = list()
  len list = list()
  # end_time1 = list() # not needed for time truncated case
 for (i in 1:n_shift) {
   t_list[[i]] = sim_plp_tau(tau_vector[i], beta, theta)
   len_list[[i]] = length(t_list[[i]])
  }
  event_dat = data.frame(
    shift_id = rep(1:n_shift, unlist(len_list)),
   event_time = Reduce(c, t_list)
  start_end_dat = data.frame(
   shift_id = 1:n_shift,
   start_time = rep(0, n_shift),
   end_time = tau_vector #difference2
  return(list(event_dat = event_dat,
              start_end_dat = start_end_dat,
              shift_length = unlist(len_list)))
# plot events
plot_events = function(event_dat, start_end_dat, cross_size = 2){
 p = event_dat %>%
    ggplot(aes(x = event_time, y = shift_id)) +
    geom_point(alpha = 0.8, shape = 4, color = 'red', size = cross_size) +
    scale_y_continuous("shift ID",
                       labels = as.character(start_end_dat$shift_id),
```

2 Jump Power Law Process (JPLP)

2.1 JPLP intensity function

A Bayesian hierarchical JPLP has the following intensity function:

$$\lambda_{\text{JPLP}}(t|d, s, r, \beta, \gamma_{0,d}, \gamma, \mathbf{X}_d, \mathbf{W}) = \begin{cases} \kappa^0 \lambda(t|\beta, \gamma_{0,d}, \gamma, \mathbf{X}_d, \mathbf{W}) & 0 \le t \le a_{d,s,1} \\ \kappa^1 \lambda(t|\beta, \gamma_{0,d}, \gamma, \mathbf{X}_d, \mathbf{W}) & a_{d,s,1} \le t \le a_{d,s,2} \\ \dots & \dots \\ \kappa^{R-1} \lambda(t|\beta, \gamma_{0,d}, \gamma, \mathbf{X}_d, \mathbf{W}) & a_{d,s,R-1} \le t \le a_{d,s,R} \end{cases}$$

$$= \kappa^{r-1} \lambda(t|d, s, r, \kappa, \beta, \gamma_{0,d}, \gamma, \mathbf{X}_d, \mathbf{W}) \quad a_{d,s,r-1} \le t \le a_{d,s,r},$$

$$(1)$$

where the introduced parameter κ is the percent of intensity function recovery once the driver takes a break. We assume that this κ is constant across drivers and shifts.

2.2 JPLP mean function

Let T_1, T_2, \ldots be random variables representing the event times of a nonhomogeneous Poisson process with continuous expectation function $\Lambda(t)$, and let N_t represent the total number of events occurring before time t in the process. Then, conditional on the number of events $N_{t_0} = n$, the event times T_1, T_2, \ldots, T_n are distributed as order statistics from a sample with distribution function $F(t) = \Lambda(t)/\Lambda(t_0)$ for $t \in [0, t_0]$.

This is a generalization of the result for homogeneous Poisson processes. It naturally gives rise to the following algorithm for generating random variates from a nonhomogeneous Poisson process with expectation function $\Lambda(t)$ in a fixed interval $[0, t_0]$.

- (1) Generate $n \sim \text{Poisson}(\Lambda(t_0))$.
- (2) Independently generate n random variates t'_1, t'_2, \dots, t'_n from the cdf $F(t) = \Lambda(t)/\Lambda(t_0)$.
- (3) Order t'_1, t'_2, \dots, t'_n to obtain $t_1 = t'_{(1)}, t_2 = t'_{(2)}, \dots, t_n = t'_{(n)}$.
- (4) Deliver t_1, t_2, \ldots, t_n .

2.2.1 Mean function $\Lambda(t)$

```
# Mean function Lambda for JPLP
Lambda_PLP = function(t, beta = 1.5, theta = 4) return((t/theta)^beta)
Lambda_JPLP = function(t,
```

```
tau = 12,
                  kappa = 0.8,
                  t_{trip} = c(3.5, 6.2, 9),
                  beta = 1.5,
                  theta = 4)
{
 t_{trip1} = c(0, t_{trip})
 n_trip = length(t_trip1)
 comp = Lambda_PLP(t_trip, beta, theta)
 kappa_vec0 = rep(kappa, n_trip - 1)^(0:(n_trip - 2))
 kappa_vec1 = rep(kappa, n_trip - 1)^(1:(n_trip - 1))
 cum_comp0 = comp*kappa_vec0
  cum_comp1 = comp*kappa_vec1
  index_trip = max(cumsum(t > t_trip1)) - 1
 if(index trip == 0){
    return((t/theta)^beta)
 }else{
    return(sum(cum_comp0[1:index_trip]) - sum(cum_comp1[1:index_trip]) +
             kappa^index_trip*(t/theta)^beta)
 }
}
```

2.2.2 Test the mean function $\Lambda(t)$

```
# test Lambda_JPLP
kappa = 0.8
t_{trip} = c(3.5, 6.2, 9)
beta = 1.5
theta = 4
